The invention relates to fields of microbiology and virology.

BACKGROUND

[0002] There are three types of influenza virus: A, B, and C, which vary greatly in their epidemiological pattern. Influenza A virus is both the best characterized and the most serious threat to public health, capable of inducing massive epidemics or pandemics. This virus is also highly variable antigenically, making effective vaccine production difficult.

[0003] A vaccine to influenza would be one of the most efficacious, safe, nontoxic, and economical weapons to prevent disease and to control the spread of the disease. The primary aim of vaccination is to activate the adaptive specific immune response, primarily to generate B and T lymphocytes against antigen(s) associated with the disease or the disease agent.

[0004] Currently some vaccines against influenza are available and primarily consist of inactivated vaccines. These vaccines can comprise two type A antigens (e.g., H1N1 and H3N2) and one type B antigen. The available vaccines typically include whole virion, split-product, and subunit vaccines. Generally, these vaccines are effective in up to 90% of vaccinated individuals if the vaccines closely match the identity of the emerging epidemic. However, they need to be updated each year to keep pace with antigenic drift of the influenza virus.

[0005] Moreover, a cold-adapted live attenuated intra-nasal vaccine (LAIV) against seasonal influenza has been recently described. Cross-protective immunity was demonstrated in a study which reported protection against a H3N2 virus in cotton rats infected with a H1N1 strain. However, one major concern linked with LAIV is the possibility of genetic reversion and re-assortment with wild-type influenza viruses, resulting in a new, potentially infectious strain.

[0006] The application or invention addresses these and other problems in the influenza vaccine field by providing a vaccine and composition that elicits an immune response against one or more influenza strains using a mutated Bordetella strain as the active principle agent.

[0007] In addition, the related art describes various types of vaccines and compositions using Bordetella strains (WO2007104451 and WO2003102170) to induce immune responses against, e.g., Bordetella bacteria capable of causing whooping cough in humans; however, the art fails to disclose methods or compositions for eliciting an immune response to an influenza virus in a mammal using the methods, compositions, and/or vaccines of the invention.

[0008] Thus, a need exists for a novel influenza vaccine capable of providing broad protection against diseases caused by influenza virus infection.

BRIEF SUMMARY

[0009] The application or invention relates to compositions and vaccines that include a mutated Bordetella strain for treating or preventing an influenza infection in a mammal. In addition, the application further provides, and the means of the invention are suitable for implementation in methods for protecting a mammal against infection by influenza and/or eliciting an immune response against an influenza virus in a mammal using the composition or vaccine. The invention is defined by the appended claims.

[0010] In one aspect, the application provides, and the means of the invention are suitable for implementation in a method of eliciting an immune response against an influenza virus in a mammal, comprising: administering a mutated Bordetella strain to the mammal, wherein the strain comprises a mutated pertussis toxin (ptx) gene, a deleted or mutated dermonecrotic (dnt) gene, and a heterologous ampG gene. In some aspects, the Bordetella strain comprises a Bordetella pertussis strain. In some such aspects, the wild-type Bordetella strain ampG gene is replaced by an E. coli ampG gene. In other aspects, the mutation of the ptx gene comprises the substitution of an amino acid involved in substrate binding and/or an amino acid involved in catalysis. In some such aspects, the substitution of the amino acid involved in substrate binding comprises K9R and the substitution of the amino acid involved in catalysis comprises E129G. In some aspects, the Bordetella strain comprises a triple mutant strain. In some such aspects, the Bordetella strain comprises a BPZE1 strain. In other such aspects, the Bordetella strain is attenuated. In some aspects, the Bordetella strain comprises a live strain. In other aspects, the Bordetella strain does not comprise a heterologous gene other than the heterologous ampG gene. In some aspects, the Bordetella strain does not comprise a heterologous expression platform to carry heterologous antigens to the respiratory mucosa of the mammal. In other aspects, the methods further comprise the prevention or treatment of the influenza infection in the mammal. In some aspects, the Bordetella strain is administered prior to the influenza infection. In some such aspects, the Bordetella strain is administered about 6 weeks or more prior to the influenza infection. In other such aspects, the Bordetella strain is administered prior to the influenza infection. In some such aspects, the influenza virus comprises H3 or H1. In other aspects, the influenza virus comprises N3 or N1.

[0011] In some aspects, the influenza virus comprises H3 and N2. In other aspects, the influenza virus comprises H1 and N1. In some aspects, the immune response comprises a Th1 immune response. In some aspects, the strain is administered to the mammal by subcutaneous (s.c.), intradermal (i.d.), intramuscular (i.m.), intravenous (i.v.), oral, or intranasal administration; or by injec-
In another aspect, the application provides and aspects, the mammal is a human. In some aspects, the influenza infection is more than about 50%. In other aspects, a level of protection against the influenza infection is more than about 60%. In other aspects, a level of protection against the influenza infection is more than about 50%. In some aspects, the mammal is a human.

In another aspect, the application provides and the means of the invention are suitable for implementation in methods of eliciting a protective immune response against an H3N2 influenza virus in a human, comprising: intranasally administering a live and attenuated BPZE1 strain to the human prior to infection of the human by the H3N2 influenza virus, wherein the strain does not comprise a heterologous expression platform to carry heterologous antigens to the respiratory mucosa of the human.

In another aspect, the application provides and the means of the invention are suitable for implementation in methods of eliciting an immune response against an influenza virus in a human, comprising: administering a live Bordetella strain to the human, wherein the strain does not comprise a heterologous expression platform to carry heterologous antigens to the respiratory mucosa of the human.

In another aspect, the application provides and the means of the invention are suitable for implementation in methods of protecting a mammal against a disease caused by an influenza infection, comprising: administering to the mammal a mutated Bordetella strain comprising a mutated ptx gene, a deleted or mutated dnt gene, and a heterologous ampG gene.

In another aspect, the application provides and the means of the invention are suitable for implementation in providing a protective immunity against an influenza infection, comprising: administering to the mammal a mutated Bordetella strain comprising a mutated ptx gene, a deleted or mutated dnt gene, and a heterologous ampG gene.

In another aspect, the application provides a composition for treating or preventing an influenza infection in a mammal, comprising: a mutated Bordetella strain, wherein the strain comprises a mutated pertussis toxin (ptx) gene, a deleted or mutated dermonecrotic (dnt) gene, and a heterologous ampG gene. The invention relates to a composition for use in the treatment or prevention of an influenza infection in a mammal, wherein said composition comprises an attenuated Bordetella strain, wherein said attenuated Bordetella strain is a mutated Bordetella strain comprising a mutated pertussis toxin (ptx) gene, a deleted or mutated dermonecrotic (dnt) gene, and a heterologous ampG gene, and wherein said mutated Bordetella strain does not comprise a heterologous expression platform carrying heterologous antigens, said heterologous expression platform being used to deliver the heterologous antigens to the respiratory mucosa of a mammal. In some aspects, the Bordetella strain comprises a Bordetella pertussis strain. In other aspects, the wild-type Bordetella strain ampG gene is replaced by an E. coli ampG gene. In some aspects, the mutation of the ptx gene comprises the substitution of an amino acid involved in substrate binding and/or an amino acid involved in catalysis. In other aspects, the substitution of the amino acid involved in substrate binding comprises K9R and the substitution of the amino acid involved in catalysis comprises E129G. In some aspects, the Bordetella strain comprises a Bordetella pertussis strain. In other aspects, a level of protection against the influenza infection is more than about 50%. In some aspects, the mammal is a human.

Figure 1 shows protection rate of BPZE1-treated mice against lethal challenge with mouse-adapted H3N2 virus. Adult Balb/c mice were nasally administered with 5 x 10⁶ cfu of BPZE1 bacteria and challenged either 3 weeks (solid square) or 6 weeks (solid triangle) later with a lethal dose (2LD50) of mouse-adapted H3N2 virus. Body weight changes were monitored daily and mice were euthanized when body weight loss exceeded 20% of the original body weight. Survival rates were compared to non-treated mice (solid lozenge). 10 animals per group were assessed. Results are representative of three independent experiments.

Figure 2 shows protection rates against lethal challenge with mouse-adapted H3N2 virus in mice treated with dead versus live BPZE1 bacteria. Adult Balb/c mice were nasally administered with 5 x 10⁶ cfu of live (solid triangle) or dead (solid square) BPZE1 bacteria, and challenged 6 weeks later with a lethal dose (2LD50) of mouse-adapted H3N2 virus. Body weight changes were monitored daily and mice were euthanized when body weight loss exceeded
20% of the original body weight. Survival rates were compared to non-treated mice (solid lozenge). 10 animals per group were assessed. Results are representative of two independent experiments.

**Figure 3** shows protection rate against lethal challenge with mouse-adapted H3N2 virus in mice treated twice with live BPZE1 bacteria. Adult Balb/c mice were nasally administered twice at a 4-week interval with $5 \times 10^6$ cfu of BPZE1 bacteria (solid square) and challenged 4 weeks later with a lethal dose (2LD50) of mouse-adapted H3N2 virus. Body weight changes were monitored daily and mice were euthanized when body weight loss exceeded 20% of the original body weight. Survival rates were compared to non-treated mice (solid lozenge). 10 animals per group were assessed. Results are representative of two independent experiments.

**Figure 4** shows protection rate of BPZE1-treated mice against lethal challenge with H1N1 influenza A virus. Adult Balb/c mice were nasally administered three times at 4-week and 3-week intervals (solid triangle) with $5 \times 10^6$ cfu of live BPZE1 bacteria. The animals were challenged with a lethal dose (4 LD50) of A/PR/8/34 (H1N1) influenza A virus 2 weeks after the last BPZE1 treatment. Body weight changes were monitored daily and mice were euthanized when body weight loss exceeded 20% of the original body weight. Survival rates were compared to non-treated mice (solid lozenge). 10 animals per group were assessed. Results are representative of 2 independent experiments.

**Figure 5** shows viral load quantification in the lungs of protected versus non-protected mice. Adult Balb/c mice were nasally administered twice at a 4-week interval with $5 \times 10^6$ cfu of live BPZE1 bacteria and challenged 4 weeks later with a lethal dose (2LD50) of mouse-adapted H3N2 virus. Five animals per group were sacrificed 3 days post-viral challenge, their lungs were harvested and individually processed for in vitro determination of TCID$_{50}$ upon infection of MDCK cells. The viral load was compared with that obtained in non-treated mice. Results are representative of 3 independent experiments.

**Figure 6** shows lung histology and cellular infiltrates and CD3$^+$ T cell population in the lungs in BPZE1-treated versus non-treated mice after lethal viral challenge. Adult Balb/c mice were nasally administered with $5 \times 10^6$ cfu of live BPZE1 bacteria and challenged 6 weeks later with a lethal dose (2LD50) of mouse-adapted H3N2 virus. Three days post-viral challenge, mice were euthanized and their lungs were individually processed for histology analysis (A) or broncho-alveolar lavages for analysis of the cellular infiltrates (B). Legend A: Infected control mice displayed severe inflammation, pulmonary edema (black arrow) and severe necrotizing bronchitis with necrotic cell debris (open arrow). Infected BPZE1-treated mice showed only minimal inflammation and airway damage, and mild peribronchular damage. Representative fields are shown. Results were equivalent in more than 40 fields analyzed per group (>5 fields/section, 2 sections/mouse and 4 mice/group). Legend B: a, naive mice non-challenged; b, naive mice challenged with H3N2 virus; c, BPZE1-treated mice non-challenged; d, BPZE1-treated mice challenged with H3N2 virus. Four animals per time point per group were individually assessed. **, p ≤ 0.01; ***, p ≤ 0.001. Results are representative of two independent experiments. (C) FACS analysis of the CD3$^+$ T cell population in the mice lungs. 3 days or 5 days after lethal H3N2 influenza virus challenge, non-treated control mice and mice treated twice with BPZE1 were euthanized and CD3$^+$ T cell population in their lungs were analyzed by flow cytometry. Four animals per time point per group were individually assessed. Results are expressed in percentage of CD3$^+$ T cells in the total lung cell population. mean ± SD. Legend: a, naive mice non-challenged; b, BPZE1-treated mice non-challenged; c, naive mice challenged with H3N2 virus and sacrificed 3 days later; d, BPZE1-treated mice challenged with H3N2 virus and sacrificed 3 days later; e, naive mice challenged with H3N2 virus and sacrificed 5 days later; f, BPZE1-treated mice challenged with H3N2 virus and sacrificed 5 days later. ***, p ≤ 0.001.

**Figure 7** shows pro- and anti-inflammatory cytokine and chemokine profiles in the BPZE1-treated versus non-treated mice after lethal H3N2 viral challenge. Adult Balb/c mice were nasally administered twice at a 4-week interval with $5 \times 10^6$ cfu of live BPZE1 bacteria and were challenged with a lethal dose (2LD50) of mouse-adapted H3N2 virus 4 weeks after the last administration. One and three days post-viral challenge, five mice per group and per time point were sacrificed and broncho-alveolar lavage fluids (BALFs) were collected. 14 inflammation-related cytokines and chemokines were measured in each individual BALF sample. Legend: 1, non-treated non-challenged mice; 2, BPZE1-treated non-challenged mice; 3, non-treated challenged mice and sacrificed 1 day post-challenge; 4, BPZE1-treated challenged mice and sacrificed 1 day post-challenge; 5, non-treated challenged mice and sacrificed 3 days post-challenge; 6, BPZE1-treated challenged mice and sacrificed 3 days post-challenge. * , p ≤ 0.05; **, p ≤ 0.01; ***, p ≤ 0.001.

**Figure 8** shows role of the *B. pertussis-specific* immunity in the cross-protection. (A) Naive (open triangle) or anti-H3N2 (solid circle) or anti-BPZE1 (open circle) immune serum was ip. injected to adult naive Balb/c mice one day prior to lethal challenge (2LD50) with mouse-adapted H3N2 virus. Body weight changes were monitored daily and mice were euthanized when body weight loss exceeded 20% of the original body weight. Survival rates were com-

5
pared to non-treated mice (solid triangle). 10 animals per group were assessed. (B) & (C). Adult Balb/c mice were nasally administered with 5 x 10^6 cfu of live BPZE1 bacteria and 6 weeks later the animals were euthanized and their spleens were harvested. Pooled (B) or individual (C) splenocytes from 6 animals were stimulated with either BPZE1 lysate or heat-inactivated H3N2 virus particles. 3H-thymidine incorporation (B) and IFN-γ ELISPOT assay (C) were performed as described below. Representative of two different experiments, both showed similar results; mean±SD; *, p<0.05, ***, p<0.001.

DETAILED DESCRIPTION

INTRODUCTION AND OVERVIEW

[0021] The application or invention relates to compositions and vaccines as defined by the appended claims that include a mutated Bordetella strain for treating or preventing influenza infection in a mammal. In addition, the application further provides or the means of the invention are suitable for implementation in methods for protecting a mammal against infection by influenza and/or eliciting an immune response against an influenza virus in a mammal using the composition or vaccine. The invention relates to a composition for use in the treatment or prevention of an Influenza infection in a mammal, wherein said composition comprises an attenuated Bordetella strain, wherein said attenuated Bordetella strain is a mutated Bordetella strain comprising a mutated pertussis toxin (ptx) gene, a deleted or mutated dermonecrotic (dnt) gene, and a heterologous ampG gene, and wherein said mutated Bordetella strain does not comprise a heterologous expression platform carrying heterologous antigens, said heterologous expression platform being used to deliver the heterologous antigens to the respiratory mucosa of a mammal.

[0022] Terms used in the claims and specification are defined as set forth below unless otherwise specified.

[0023] As used herein, the abbreviation "PTX" refers to pertussis toxin, which synthesizes and secretes an ADP-ribosylating toxin. PTX is comprised of five different subunits (named S1-S5) with each complex containing two copies of S4. The subunits are arranged in an A-B structure. The A component is enzymatically active and is formed from the S1 subunit, while the B component is the receptor binding portion and is made up of subunits S2-S5.

[0024] As used herein the abbreviation "DNT" refers to pertussis dermonecrotic toxin, which is a heat labile toxin that can induce localized lesions in mice and other laboratory animals when it is injected intradermally.

[0025] As used herein the abbreviation "TCT" refers to tracheal cytotoxin, which is a virulence factor synthesized by Bordetellae. TCT is a peptidoglycan fragment and has the ability to induce interleukin-1 production and nitric oxide synthase. It has the ability to cause stasis of cilia and has lethal effects on respiratory epithelial cells.

[0026] The term "attenuated" refers to a weakened, less virulent Bordetella strain that is capable of stimulating an immune response and creating protective immunity, but does not generally cause illness.

[0027] The term "rapid protective immunity" means that immunity against Bordetella is conferred in a short time after administration of the mutated Bordetella strain of the application or suitable for the invention.

[0028] The term "Bordetella strain" or "strain" includes strains from Bordetella pertussis, Bordetella parapertussis, and Bordetella bronchiseptica.

[0029] The term "child" is meant to be a person or a mammal between 0 months and 18 years of age.

[0030] "Treating" refers to any indicia of success in the treatment or amelioration or prevention of the disease, condition, or disorder, including any objective or subjective parameter such as abatement; remission; diminishing of symptoms or making the disease condition more tolerable to the patient; slowing in the rate of degeneration or decline; or making the final point of degeneration less debilitating. The treatment or amelioration of symptoms can be based on objective or subjective parameters; including the results of an examination by a physician. Accordingly, the term "treating" includes the administration of the compounds or agents of the application or invention to prevent or delay, to alleviate, or to arrest or inhibit development of the symptoms or conditions associated with a disease, condition or disorder as described herein. The term "therapeutic effect" refers to the reduction, elimination, or prevention of the disease, symptoms of the disease, or side effects of the disease in the subject. "Treating" or "treatment" using the methods of the application or the means of the invention includes preventing the onset of symptoms in a subject that can be at increased risk of a disease or disorder associated with a disease, condition or disorder as described herein, but does not yet experience or exhibit symptoms, inhibiting the symptoms of a disease or disorder (slowing or arresting its development), providing relief from the symptoms or side effects of a disease (including palliative treatment), and relieving the symptoms of a disease (causing regression). Treatment can be prophylactic (to prevent or delay the onset of the disease, or to prevent the manifestation of clinical or subclinical symptoms thereof) or therapeutic suppression or alleviation of symptoms after the manifestation of the disease or condition.

[0031] "Concomitant administration" of a known drug (or other compound) with the composition of the application or invention means administration of the drug (or other compound) together with the composition at such time that both the known drug (or other compound) will have a therapeutic effect or diagnostic effect. Such concomitant administration can involve concurrent (i.e., at the same time), prior, or subsequent administration of the drug (or other compound) with respect to the administration of a composition of the application or invention.
A person of ordinary skill in the art would have no difficulty determining the appropriate timing, sequence, and dosages of administration for particular drugs (or other compounds) together with compositions of the application or invention.

[0032] The terms "protection" and "prevention" are used herein interchangeably and mean that an infection by influenza is impeded.

[0033] "Prophylaxis vaccine" means that this vaccine prevents influenza infection upon future exposure.

[0034] The term "immunogenic composition" or "composition" means that the composition can induce an immune response and is therefore antigenic. By "immune response" means any reaction by the immune system. These reactions include the alteration in the activity of an organism's immune system in response to an antigen and can involve, for example, antibody production, induction of cell-mediated immunity, complement activation, or development of immunological tolerance.

[0035] As used herein, the term "disease" has the meaning generally known and understood in the art and comprises any abnormal condition in the function or well being of a host individual. A diagnosis of a particular disease by a healthcare professional can be made by direct examination and/or consideration of results of one or more diagnostic tests.

[0036] The terms "live vaccine composition", "live vaccine", "live bacterial vaccine", and similar terms refer to a composition comprising a strain of live Bordetella bacteria that provides at least partial protective immunity against influenza.

[0037] The terms "oral", "enteral", "enterally", "orally", "non-parenteral", "non-parenterally", and the like, refer to administration of a compound or composition to an individual by a route or mode along the alimentary canal. Examples of "oral" routes of administration of a composition include, without limitation, swallowing liquid or solid forms of a vaccine composition from the mouth, administration of a vaccine composition through a nasojejunal or gastrostomy tube, intraduodenal administration of a vaccine composition, and rectal administration, e.g., using suppositories that release a live bacterial vaccine strain described herein.

[0038] The term "topical administration" refers to the application of a pharmaceutical agent to the external surface of the skin or the mucus membranes (including the surface membranes of the nose, lungs and mouth), such that the agent crosses the external surface of the skin or mucus membrane and enters the underlying tissues. Topical administration can result in a limited distribution of the agent to the skin and surrounding tissues or, when the agent is removed from the treatment area by the bloodstream, systemic distribution of the agent. In a preferred form, the agent is delivered by transdermal delivery, e.g., using a transdermal patch. Transdermal delivery refers to the diffusion of an agent across the skin (stratum comeum and epidermis), which acts as a barrier few agents are able to penetrate. In contrast, the dermis is permeable to absorption of many solutes and drugs, and topical administration thereof occurs more readily through skin which is abraded or otherwise stripped of the epidermis to expose the dermis. Absorption through intact skin can be enhanced by combining the active agent with an oily vehicle (e.g., creams, emollients, penetration enhancers, and the like, as described, e.g., in Remington’s Pharmaceutical Sciences, current edition, Gennaro et al., eds.) prior to application to the skin (a process known as inunction).

[0039] The term "nasal administration" refers to any form of administration whereby an active ingredient is propelled or otherwise introduced into the nasal passages of a subject so that it contacts the respiratory epithelium of the nasal cavity, from which it is absorbed into the systemic circulation. Nasal administration can also involve contacting the olfactory epithelium, which is located at the top of the nasal cavity between the central nasal septum and the lateral wall of each main nasal passage. The region of the nasal cavity immediately surrounding the olfactory epithelium is free of airflow. Thus, specialized methods must typically be employed to achieve significant absorption across the olfactory epithelium.

[0040] The term "aerosol" is used in its conventional sense as referring to very fine liquid or solid particles carried by a propellant gas under pressure to a site of therapeutic application. A pharmaceutical aerosol of the application or comprising the means of the invention contains a therapeutically active compound, which can be dissolved, suspended, or emulsified in a mixture of a fluid carrier and a propellant. The aerosol can be in the form of a solution, suspension, emulsion, powder, or semisolid preparation. Aerosols of the application or comprising the means of the invention are intended for administration as fine, solid particles or as liquid mists via the respiratory tract of a patient. Various types of propellants can be utilized including, but not limited to, hydrocarbons or other suitable gases. Aerosols of the application or comprising the means of the invention can also be delivered with a nebulizer, which generates very fine liquid particles of substantially uniform size within a gas. Preferably, a liquid containing the active compound is dispersed as droplets, which can be carried by a current of air out of the nebulizer and into the respiratory tract of the patient.

[0041] The term "ameliorating" refers to any therapeutically beneficial result in the treatment of a disease state, e.g., an influenza-related disease state, including prophylaxis, lessening in the severity or progression, remission, or cure thereof.

[0042] In general, the phrase "well tolerated" refers to the absence of adverse changes in health status that occur as a result of the treatment and would affect treatment decisions.

[0043] "Synergistic interaction" refers to an interaction in which the combined effect of two or more agents is greater than the algebraic sum of their individual effects.
There are 16 different hemagglutinin subtypes H1, H2, H3, H5, H4, H6, H7, H8, H9, H10, H11, H12, H13, H14, H15 or H16 and 9 different neuraminidase subtypes N1, N2, N3, N4, N5, N6, N7, N8, or N9, all of which have been found among influenza A viruses in wild birds. Influenza A viruses include A(H1N1) and A(H3N2), both of which are examples of influenza viruses that can be targeted by the means of the application or invention for treatment or prevention in a mammal. Diseases and symptoms typically caused by influenza virus infection can include: fever, coughing, sneezing, aches, fatigue, headache, watery eyes, nasal congestion, and abdominal pain. The means of the application or invention can be used to treat or prevent these diseases.

COMPOSITIONS

Bordetella Strains

The application provides or the means of the invention involves a mutated Bordetella strain that can be used as an immunogenic composition or a vaccine to elicit an immune response in a mammal. In one aspect, the mutated Bordetella strain contains a mutated ptx gene, a deleted or mutated dnt gene, and a heterologous ampG gene. The heterologous ampG gene product can reduce in large quantities the amount of tracheal cytotoxin that is produced. In one aspect, the strain is B. pertussis. In another aspect, the starting strain used to obtain the mutated Bordetella strain is B. pertussis. In another aspect, the strain is a triple mutant Bordetella strain. In another aspect, the Bordetella strain is identified by accession number CNCM I-3585. In another aspect, the Bordetella strain is identified by accession number V09/009169.

The starting strain which is mutated can be any Bordetella strain including Bordetella pertussis, Bordetella parapertussis, and Bordetella bronchiseptica. In one aspect the starting strain used to obtain the mutated Bordetella strain is B. pertussis. In another aspect, the strain is a triple mutant Bordetella strain. In another aspect, the Bordetella strain is identified by accession number V09/009169.

The means of the application or invention is not limited to only the mutants described above. Other additional mutations can be undertaken such as adenylate cyclase (AC) deficient mutants, lipopolysaccharide (LPS) deficient mutants, filamentous hemagglutinin (FHA), and any of the bvg-regulated components.

The construction of a mutated Bordetella strain of the application or suitable for the invention can begin with replacing the Bordetella ampG gene in the strain with a heterologous ampG gene. Any heterologous ampG gene known in the art can be used in the application or invention. Examples of these can include all gram-negative bacteria that release very small amounts of peptidoglycan fragments into the medium per generation. Examples of gram-negative bacteria include, but are not limited to: Escherichia coli, Salmonella, Enterobacteriaceae, Pseudomonas, Moraxella, Helicobacter, Stenotrophomonas, Legionella, and the like. Typically, by replacing the Bordetella ampG gene with a heterologous ampG gene, the amount of tracheal cytotoxin (TCT) produced in the resulting strain expresses less than 1% residual TCT activity. In another aspect, the amount of...
TCT activity expressed by the resulting strain is between about 0.6% to 1% residual TCT activity or about 0.4% to 3% residual TCT activity or about 0.3% to 5% residual TCT activity.

**[0056]** PTX is a major virulence factor responsible for the systemic effects of B. pertussis infections, as well as one of the major protective antigens. Due to its properties, the natural ptx gene can be replaced by a mutated version so that the enzymatically active moiety S1 codes for an enzymatically inactive toxin, but the immunogenic properties of the pertussis toxin are not affected. This can be accomplished by replacing the lysine (Lys) at position 9 of the sequence with an arginine (Arg) (K9R). Furthermore, a glutamic acid (Glu) at position 129 can be replaced with a glycine (Gly) (E129G). Generally these amino acid positions are involved in substrate binding and catalysis, respectively. In other aspects, other mutations can also be made such as those described in U.S. Patent No. 6,713,072; as well as any known or other mutations able to reduce the toxicity of the strain. In one aspect, allelic exchange can first be used to delete the ptx operon and then to insert a mutated version.

**[0057]** In another aspect of the application or invention, the dnt gene can be removed from the Bordetella strain using allelic exchange. Besides the total removal, the enzymatic activity can also be inhibited by a point mutation. Since DNT is constituted by a receptor-binding domain in the N-terminal region and a catalytic domain in the C-terminal part, a point mutation in the dnt gene to replace Cys-1305 to Ala-1305 inhibits the enzyme activity of DNT (Kashimoto T., Katahira J, Cornejo WR, Masuda M, Fukuhara A, Matsuzawa T, Ohnishi T, Horiguchi Y. (1999) Identification of functional domains of Bordetella dmemucrotoxin. Infect. Immun. 67: 3727-32.).

**[0058]** Besides allelic exchange to insert the mutated ptx gene and the inhibited or deleted dnt gene, the open reading frame of a gene can be interrupted by insertion of a genetic sequence or plasmid. This method is also contemplated in the application or invention. Other methods of generating mutant strains are generally well known in the art.

**[0059]** In one aspect of the application or invention, the mutated strain is called a BPZE1 strain and has been deposited with the Collection Nationale de Cultures de Microorganismes (CNCM) in Paris, France under the Budapest Treaty on March 9, 2006 and assigned the number CNCM I-3585. The mutations introduced into BPZE1 generally result in attenuation, but also allow the bacteria to colonize and persist. Thus, in another aspect, the application or invention provides BPZE1, which can induce mucosal immunity and systemic immunity when administered to a mammal in need thereof. A BPZE1 recombinant strain was constructed which expresses the extracellular portion of the M2 protein from influenza virus. It is highly conserved among all influenza A viruses and has been shown to induce an antibody-mediated protection against influenza A viruses. The recombinant M2e-producing BPZE1 strain can trigger (for example, upon nasal administration of the live bacteria) substantial anti-M2e antibody responses (local and systemic), allowing a significant protection against H1N1 and H3N2 challenges comparable to the BPZE1 bacteria alone.

**[0060]** The mutated Bordetella strains of the application or suitable for the invention can be used in immunogenic compositions for the treatment or prevention of influenza virus infections. Such immunogenic compositions are useful to raise an immune response, either an antibody response and or a T cell response in mammals. For example, the T cell response can be such that it protects a mammal against influenza infection or against its consequences/diseases/symptoms.

**[0061]** The mutated Bordetella strains of the application or suitable for the invention can be used as live strains in vaccines or immunogenic compositions. In one aspect, the live strains are used for nasal administration, while the chemically-or heat killed strains can be used for systemic or mucosal administration. In other aspects the strains are attenuated.

**[0062]** In other aspects of the application or invention, the strains do not include any heterologous genes other than the heterologous ampG gene described above. In yet other aspects, the strains do not include a heterologous expression platform (See, e.g., WO2007104451). Typically, heterologous expression platforms carry heterologous antigens. In one aspect, the heterologous expression platform can be used to deliver the heterologous antigens to the respiratory mucosa of a mammal.

**Adjuvants**

**[0063]** Compositions of the application or invention can be administered in conjunction with other immunoregulatory agents, including adjuvants. As used herein, the term "adjuvant" refers to a compound or mixture that enhances an immune response. In particular, compositions can include an adjuvant. Adjuvants for use with the means of the application or invention can include, but are not limited to, one or more of the following set forth below:

**Mineral Containing Adjuvant Compositions**

**[0064]** Mineral containing compositions suitable for use as adjuvants in the means of the application or invention include mineral salts, such as aluminum salts and calcium salts. The means of the application or invention include mineral salts such as hydroxides (e.g., oxyhydroxides), phosphates (e.g., hydroxyphosphates, orthophosphates), sulfates, and the like (e.g., see chapters 8 & 9 of Vaccine Design ... (1995) eds. Powell & Newman. ISBN: 030644867X. Plenum.), or mixtures of different mineral compounds (e.g., a mixture of a phosphate and...
a hydroxide adjuvant, optionally with an excess of the phosphate), with the compounds taking any suitable form (e.g., gel, crystalline, amorphous, and the like), and with adsorption to the salt(s) being preferred. The mineral containing compositions can also be formulated as a particle of metal salt (WO/0023105).

**Oil-Emulsion Adjuvants**

**[0065]** Aluminum salts can be included in compositions of the application or invention such that the dose of Al₃⁺ is between 0.2 and 1.0 mg per dose.

**Oil-emulsion adjuvants**

**[0066]** Oil-emulsion compositions suitable for use as adjuvants in the means of the application or invention can include squalene-water emulsions, such asMF59 (5% Squalene, 0.5% Tween 80, and 0.5% Span 85, formulated into submicron particles using a microfluidizer). See, e.g., WO90/14837. See also, Poddà, "The adjuvan

**[0067]** In other related aspects, adjuvants for use in the compositions are submicron oil-in-water emulsions. Examples of submicron oil-in-water emulsions for use herein include squalene-water emulsions optionally containing varying amounts of MTP-PE, such as a submicron oil-in-water emulsion containing 4-5% w/v squalene, 0.25-1.0% w/v Tween 80 (polyoxyethylene sorbitan monooleate), and/or 0.25-1.0% Span 85 (sorbitan trioleate), and, optionally, N-acetyl ramifications of the native viral genome. The viral proteins can be recombinantly produced or isolated from whole viruses. These viral proteins suitable for use in virosomes or VLPs are generally non-path
genic, non-replicating and generally do not contain any

**Saponin Adjuvant Formulations**

**[0070]** Saponin formulations, can also be used as adjuvants in the means of the application or invention. Saponins are a heterologous group of sterol glycosides and triterpenoid glycosides that are found in the bark, leaves, stems, roots and even flowers of a wide range of plant species. Saponin from the bark of the Quillaja saponaria Molina tree have been widely studied as adjuvants. Sapo

**[0071]** Saponin compositions have been purified using High Performance Thin Layer Chromatography (HPLC) and Reversed Phase High Performance Liquid Chromatography (RP-HPLC). Specific purified fractions using these techniques have been identified, including QS7, QS17, QS18, QS21, QH-A, QH-B and QH-C. A method of production of QS21 is disclosed in U.S. Pat. No. 5,057,540. Saponin formulations can also comprise a sterol, such as cholesterol (see WO96/33739).

**[0072]** Combinations of saponins and cholesterol can be used to form unique particles called ISCOMs. ISCOMs typically also include a phospholipid such as phosphatidylethanolamine or phosphatidylcholine. Any known saponin can be used in ISCOMs. For example, an ISCOM can include one or more of Quil A, QHA and QHC. ISCOMs are further described in EP1099942, WO96/11711, and WO96/33739. Optionally, the ISCOMs can be devoid of additional detergent. See WO00/07621.

**Virosomes and Virus Like Particles (VLPs)**

**[0074]** Virosomes and Virus Like Particles (VLPs) can also be used as adjuvants in the means of the application or invention. These structures generally contain one or more proteins from a virus optionally combined or formulated with a phospholipid. They are generally non-pathogenic, non-replicating and generally do not contain any of the native viral genome. The viral proteins can be recombinantly produced or isolated from whole viruses. These viral proteins suitable for use in virosomes or VLPs include proteins derived from influenza virus (such as HA or NA), Hepatitis B virus (such as core or capsid proteins), Hepatitis E virus, measles virus, Sindbis virus, Rotavirus, Foot-and-Mouth Disease virus, Retrovirus, Norwalk virus, human Papilloma virus, HIV, RNA-phages, QB-
phage (such as coat proteins), GA-phage, fr-phage, AP205 phage, and Ty (such as retrotransposon Ty protein pl).

**Bacterial or Microbial Derivatives**

**[0075]** Adjuvants suitable for use in the means of the application or invention include bacterial or microbial derivatives such as:

1. Non-toxic derivatives of enterobacterial lipopolysaccharide (LPS)

**[0076]** Such derivatives include Monophosphoryl lipid A (MPL) and 3-O-deacylated MPL (3 dMPL). 3 dMPL is a mixture of 3 De-O-acylated monophosphoryl lipid A with 4, 5 or 6 acylated chains. An example of a "small particle" form of 3 De-O-acylated monophosphoryl lipid A is disclosed in EP 0 689 454. Such "small particles" of 3 dMPL are small enough to be sterile filtered through a 0.22 micron membrane (see EP 0 689 454). Other non-toxic LPS derivatives include monophosphoryl lipid A mimics, such as aminoalkyl glucosaminide phosphate derivatives e.g., RC-529. See Johnson et al., Bioorg Med Chem Lett 9: 2273-2278, 1999.

2. Lipid A Derivatives

**[0077]** Lipid A derivatives can include derivatives of lipid A from *Escherichia coli* such as OM-174. OM-174 is described for example in Meraldi et al., "OM-174, a New Adjuvant with a Potential for Human Use, Induces a Protective Response with Administered with the Synthetic C-Terminal Fragment 242-310 from the circumsporozoite protein of Plasmodium berghei", Vaccine 21: 2485-2491, 2003; and Pajak, et al., "The Adjuvant OM-174 Induces both the migration and maturation of murine dendritic cells in vivo", Vaccine 21: 836-842, 2003.

3. Immunostimulatory oligonucleotides

**[0078]** Immunostimulatory oligonucleotides suitable for use as adjuvants in the means of the application or invention can include nucleotide sequences containing a CpG motif (a sequence containing an unmethylated cytosine followed by guanosine and linked by a phosphate bond). Bacterial double stranded RNA or oligonucleotides containing palindromic or poly(dG) sequences have also been shown to be immunostimulatory.

**[0082]** Bacterial ADP-ribosylating toxins and detoxified derivatives thereof.

**Bioadhesives and Mucoadhesives**

[0083] Bioadhesives and mucoadhesives can also be used as adjuvants in the means of the application or invention. Suitable bioadhesives can include esterified hyaluronic acid microspheres (Singh et al., J. Cont. Rele. 70:267-276, 2001) or mucoadhesives such as cross-linked derivatives of poly(acrylic acid), polyvinyl alcohol, polyvinyl pyrrolidone, polyacrylamides and carboxymethylcellulose. Chitosan and derivatives thereof can also be used as adjuvants in the means of the application or invention. See, for example, WO99/27960.

**Adjuvant Microparticles**

[0084] Microparticles can also be used as adjuvants in the means of the application or invention. Microparticles (i.e., a particle of about 100 nm to about 150 μm in diameter, or 200 nm to about 30 μm in diameter, or about 500 nm to about 10 μm in diameter) formed from materials that are biodegradable and/or non-toxic (e.g., a poly(alpha-hydroxy acid), a polyhydroxybutyric acid, a polyorthoester, a polyanhydride, a polycaprolactone, and the like), with poly(lactide-co-glycolide) are envisioned, optionally treated to have a negatively-charged surface (e.g., with SDS) or a positively-charged surface (e.g., with a cationic detergent, such as CTAB).

**Adjuvant Liposomes**

[0085] Examples of liposome formulations suitable for use as adjuvants are described in U.S. Pat. No. 6,090,406, U.S. Pat. No. 5,916,588, and EP 0 626 169.

I. Polyoxyethylene Ether and Polyoxyethylene Ester Formulations

[0086] Adjuvants suitable for use in the means of the application or invention can also include polyoxyethylene ethers and polyoxyethylene esters. WO99/52549. Such formulations can further include polyoxyethylene sorbitan ester surfactants in combination with an octoxynol (WO01/21207) or all peroxides and alkyl ethers or ester surfactants in combination with at least one additional non-ionic surfactant such as an octoxynol (WO01/21152).

[0087] In some aspects, polyoxyethylene ethers can include: polyoxyethylene-9-lauryl ether (laureth 9), polyoxyethylene-9-stearyl ether, polyoxyethylene-8-stearyl ether, polyoxyethylene-4-lauryl ether, polyoxyethylene-35-lauryl ether, or polyoxyethylene-23-lauryl ether.

**Polyphosphazene (PCPP)**

**Muramyl Peptides**

[0089] Examples of muramyl peptides suitable for use as adjuvants in the means of the application or invention can include N-acetyl-muramyl-L-threonyl-D-isoglutamine (thr-MDP), N-acetyl-normuramyl-1-alanyl-d-isoglutamine (nor-MDP), and N-acetylmuramyl-1-alanyl-d-isoglutaminyl-1-alanine-2-(1'2'-dipalmitoyl-sn-glycero-3-hydroxyphosphorylcholine) (MTP-PE).

**Imidazoquinolone Compounds**

**Human Immunomodulators**

[0091] Human immunomodulators suitable for use as
adjuvants in the means of the application or invention can include cytokines, such as interleukins (e.g., IL-1, IL-2, IL-4, IL-5, IL-6, IL-7, IL-12, and the like), interferons (e.g., interferon-gamma), macrophage colony stimulating factor, and tumor necrosis factor.

**Adjuvant Combinations**

[0092] The means of the application or invention can also comprise combinations of aspects of one or more of the adjuvants identified above. For example, adjuvant compositions can include:

1. A saponin and an oil-in-water emulsion (WO99/11241);
2. A saponin (e.g., QS21) + a non-toxic LPS derivative (e.g., 3 dMPL) (see WO94/00153);
3. A saponin (e.g., QS21) + a non-toxic LPS derivative (e.g., 3 dMPL) + a cholesterol;
4. A saponin (e.g., QS21) + 3 dMPL + IL-12 (optionally + a sterol) (WO98/57659);
5. Combinations of 3dMPL with, for example, QS21 and/or oil-in-water emulsions (See European patent applications 0835318, 0735898 and 0761231);
6. SAF, containing 10% Squalane, 0.4% Tween 80, 5% pluronic-block polymer L121, and thr-MDP, either microfluidized into a submicron emulsion or vortexed to generate a larger particle size emulsion.
7. Ribi adjuvant system (RAS), (Ribi Immunochem) containing 2% Squalane, 0.2% Tween 80, and one or more bacterial cell wall components from the group consisting of monophosphorylipid A (MPL), trehalose dimycolate (TDM), and cell wall skeleton (CWS), preferably MPL + CWS (Detox); and
8. One or more mineral salts (such as an aluminum salt) + a non-toxic derivative of LPS (such as 3 dPML).

[0093] Aluminum salts and MF59 are examples of adjuvants for use with infectable influenza vaccines. Bacterial toxins and bioadhesives are examples of adjuvants for use with mucosally-delivered vaccines, such as nasal vaccines. All adjuvants noted above and others as generally known in the art to one of ordinary skill can be formulated for intranasal administration using techniques well known in the art.

**Formulations and Carriers**

[0094] Methods for treatment or prevention of diseases related to influenza virus infection (described in more detail below) are also encompassed by the application or applicable to the means of the invention. Said methods include administering a therapeutically effective amount of a composition of the application or invention. The composition of the application or invention can be formulated in pharmaceutical compositions. These compositions can comprise, in addition to one or more of the strains, a pharmaceutically acceptable excipient, carrier, buffer, stabilizer, or other materials well known to those skilled in the art. Such materials should typically be non-toxic and should not typically interfere with the efficacy of the active ingredient. The precise nature of the carrier or other material can depend on the route of administration, e.g., oral, intravenous, cutaneous or subcutaneous, nasal, intramuscular, or intraperitoneal routes.

[0095] Pharmaceutical compositions for oral administration can be in tablet, capsule, powder or liquid form. A tablet can include a solid carrier such as gelatin or an adjuvant. Liquid pharmaceutical compositions generally include a liquid carrier such as water, petroleum, animal or vegetable oils, mineral oil, or synthetic oil. Physiological saline solution, dextrose, or other saccharide solution or glycols such as ethylene glycol, propylene glycol, or polyethylene glycol can be included.

[0096] For intravenous, cutaneous, or subcutaneous injection, or injection at the site of affliction, the active ingredient will be in the form of a parenterally acceptable aqueous solution which is pyrogen-free and has suitable pH, isotonicity, and stability. Those of relevant skill in the art are well able to prepare suitable solutions using, for example, isotonic vehicles such as Sodium Chloride Injection, Ringer’s Injection, or Lactated Ringer’s Injection. Preservatives, stabilisers, buffers, antioxidants, and/or other additives can be included, as required.

[0097] Administration is preferably in a "therapeutically effective amount" or "prophylactically effective amount" (as the case can be, although prophylaxis can be considered therapy), this being sufficient to show benefit to the individual. The actual amount administered, and rate and time-course of administration, will depend on the nature and severity of disease being treated. Prescription of treatment, e.g., decisions on dosage etc., is within the responsibility of general practitioners and other medical doctors, and typically takes account of the disorder to be treated, the condition of the individual patient, the site of delivery, the method of administration and other factors known to practitioners. Examples of the techniques and protocols mentioned above can be found in the latest edition of Remington’s Pharmaceutical Science, Mack Publishing Company, Easton, PA ("Remington’s").

[0098] Typically, a composition can be administered alone or in combination with other treatments, either simultaneously or sequentially dependent upon the condition to be treated.

**METHODS**

**Administration Routes**

[0099] Compositions of the application or invention will generally be administered directly to a mammal. Direct delivery can be accomplished by parenteral injection (e.g., subcutaneously, intraperitoneally, intradermal, intravenously, intramuscularly, or to the interstitial space of a tissue), or mucosally, such as by rectal, oral (e.g.,
tablet, spray), vaginal, topical, transdermal (See e.g., WO99/27961) or transcutaneous (See e.g., WO02/074244 and WO02/064162), inhalation, intranasal (See e.g., WO03/028760), ocular, aural, pulmonary or other mucosal administration. Compositions can also be administered topically by direct transfer to the surface of the skin. Topical administration can be accomplished without utilizing any devices, or by contacting naked skin with the composition utilizing a bandage or a bandage-like device (see, e.g., U.S. Pat. No. 6,348,450).

[0100] In some aspects, the mode of administration is parenteral, mucosal, or a combination of mucosal and parenteral immunizations. In other aspects, the mode of administration is parenteral, mucosal, or a combination of mucosal and parenteral immunizations in a total of 1-2 vaccinations 1-3 weeks apart. In related aspects, the route of administration includes but is not limited to intranasal delivery.

**Administration Procedures and Dosages**

[0101] The means of the application can include, and the means of the invention can be suitable for, administration of a mutated Bordetella strain to a mammal to elicit an immune response (e.g., a TH1 immune response) capable of impacting an influenza virus, e.g., H3N2. Examples of mutated Bordetella strains of the application or suitable for the invention are described above. Typically, administration of the mutated Bordetella strain is used to treat or prevent an influenza virus infection in a mammal, e.g., a human, via protective immunity against the influenza virus. In some aspects, the mutated Bordetella strain administration is used to prevent influenza infection by administration prior to the influenza virus infection. Typically, the mutated Bordetella strain is administered to a mammal about less than 1, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, or more weeks prior to the influenza virus infection.

[0102] In one aspect, the method for treating or preventing an infection by an influenza virus includes administering to a subject in need thereof a single dose of a composition of the application or invention, e.g., BPZE1. In related aspects, the administering step is performed mucosally, e.g., intranasally.

[0103] In other aspects, a composition of the application or invention is administered in more than one dose, e.g., two doses. The number of doses can vary as needed, for example the number of doses administered to a mammal can be 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, or more doses. In one aspect, the method for treating or preventing an infection by an influenza virus, includes administering to a subject in need thereof a first immunogenic composition of the application or invention (comprising e.g., BPZE1) followed by a second immunogenic composition administration (comprising e.g., BPZE1). Typically, the time range between each dose of the composition can be about 1-6 days, or about 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 20, 30, 40, 50, 60, 70, 80, 90, or more weeks. In related aspects, the time range between each dose is about 3 weeks. In other aspects, prime-boost-style methods can be employed where a composition of the application or invention can be delivered in a “priming” step and, subsequently, a composition of the application or invention is delivered in a “boosting” step.

[0104] The composition can typically be used to elicit systemic and/or mucosal immunity, for example to elicit an enhanced systemic and/or mucosal immunity. For example, the immune response can be characterized by the induction of a serum IgG and/or intestinal IgA immune response. Typically, the level of protection against influenza infection can be more than 50%, e.g., 60%, 70%, 80%, 90%, 91%, 92%, 93%, 94%, 95%, 96%, 97%, 98%, 99%, or more. In one aspect, the level of protection can be 100%. In other aspects the level of protection is less than 50%, e.g., 20%. In other aspects, the number of bacteria in each dosage is adjusted to attain an effective immune response in a mammal. The number of bacteria or cfus in each dosage can be about 1, 10, 100, 1000, 10000, 100000, 1000000, 5x10^6, or more or any dosage between said each dosage.

[0105] In other aspects the means of the application can include, or the means of the invention can be suitable for, co-administration of the composition with another agent or agents. Typically the various compositions/agents can be delivered in any order. Thus, in aspects including delivery of multiple different compositions or agents, the mutated Bordetella strain need not be all delivered before the agent, e.g., a drug, a siRNA, a miRNA, an immunogenic peptide, or a small molecule capable of effecting an influenza infection. Other examples of agents include neuraminidase inhibitors and M2 inhibitors (adamantanes). For example, the priming step can include delivery of one or more agents and the boosting can include delivery of one or more mutated Bordetella strains. In other aspects, multiple administrations of mutated Bordetella strains can be followed by multiple administrations of agents. Administrations can be performed in any order. Thus, one or more of the mutated Bordetella strains described herein and one or more agents can be co-administered in any order and via any administration route known in the art, e.g., to elicit an immune reaction.

[0106] In the application or with the means of the invention, dosage treatment can be according to a single dose schedule or a multiple dose schedule. For example, multiple doses can be used in a primary immunization schedule and/or in a booster immunization schedule. In a multiple dose schedule, the various doses can be given by the same or different routes, e.g., a parenteral prime and mucosal boost, a mucosal prime and parenteral boost, and the like. In other aspects, the dosage regime can enhance the avidity of the antibody response leading to antibodies with a neutralizing characteristic. An in-vitro neutralization assay can be used to test for neutralizing antibodies (see for example Asanaka et al.; J Virology 102: 10327, 2005; Wobus et al., PLOS Biology 2: e432;
and Dubekti et al., J Medical Virology 66: 400).

**Tests to Determine the Efficacy or Presence of an Immune Response**

[0107] One way of assessing efficacy of therapeutic treatment involves monitoring infection after administration of a composition of the application or invention. One way of assessing efficacy of prophylactic treatment involves monitoring immune responses against the antigens in the compositions of the application or invention after administration of the composition. Another way of assessing the immunogenicity of the compositions of the application or invention is to isolate the proteins or proteins mixes and to screen patient sera or mucosal secretions by immunoblot. A positive reaction between the protein and the patient serum indicates that the patient has previously mounted an immune response to the composition.

[0108] Another way of checking efficacy of therapeutic treatment involves monitoring infection after administration of the compositions of the application or invention. One way of checking efficacy of prophylactic treatment involves monitoring immune responses both systemically (such as monitoring the level of IgG1 and IgG2a production) and mucosally (such as monitoring the level of IgA production) against the antigens in the compositions of the application or invention after administration of the composition. Typically, serum specific antibody responses are determined post-immunization but pre-challenge whereas mucosal specific antibody responses are determined post-immunization and post-challenge. The immunogenic compositions of the application or invention can be evaluated in in vitro and in vivo animal models prior to host, e.g., human, administration.

[0109] The efficacy of compositions of the application or invention can also be determined in vivo by challenging animal models of infection, e.g., mice, with the compositions. The compositions can or can not be derived from the same strains as the challenge strains. In vivo efficacy models can include but are not limited to: (i) A murine infection model using human strains; (ii) a murine disease model which is a murine model using a mouse-adapted strain, such as strains which are particularly virulent in mice; and (iii) a primate model using human isolates.

[0110] The immune response induced by the application or invention can be one or both of a TH1 immune response and a TH2 response. The immune response can be an improved or an enhanced or an altered immune response. The immune response can be one or both of a systemic and a mucosal immune response. For example, the immune response can be an enhanced systemic and/or mucosal response. An enhanced systemic and/or mucosal immunity is reflected in an enhanced TH1 and/or TH2 immune response. For example, the enhanced immune response can include an increase in the production of IgG1 and/or IgG2a and/or IgA. In another aspect the mucosal immune response can be a TH2 immune response. For example, the mucosal immune response can include an increase in the production of IgA.

[0111] Typically, activated TH2 cells enhance antibody production and are therefore of value in responding to extracellular infections. Activated TH2 cells can typically secrete one or more of IL-4, IL-5, IL-6, and IL-10. A TH2 immune response can also result in the production of IgG1, IgE, IgA, and/or memory B cells for future protection. In general, a TH2 immune response can include one or more of an increase in one or more of the cytokines associated with a TH2 immune response (such as IL-4, IL-5, IL-6 and IL-10), or an increase in the production of IgG1, IgE, IgA and memory B cells. For example, an enhanced TH2 immune response can include an increase in IgG1 production.

[0112] A TH1 immune response can include one or more of an increase in CTLs, an increase in one or more of the cytokines associated with a TH1 immune response (such as IL-2, IFN-gamma, and TNF-alpha), an increase in activated macrophages, an increase in NK activity, or an increase in the production of IgG2a. For example, the enhanced TH1 immune response can include an increase in IgG2a production.

[0113] Compositions of the application or invention, in particular, an immunogenic composition comprising one or more strains of the application or suitable for the invention can be used either alone or in combination with other agents optionally with an immunoregulatory agent capable of eliciting a Th1 and/or Th2 response.

[0114] The compositions of the application or invention can elicit both a cell-mediated immune response as well as a humoral immune response to effectively address an influenza infection. This immune response will preferably induce long lasting (e.g., neutralizing) antibodies and a cell-mediated immunity that can quickly respond upon exposure to one or more infectious antigens in the future.

**Subjects and Mammals**

[0115] Compositions of the application or invention are typically for preventing or treating influenza virus strains in mammalian subjects, e.g., humans. In some aspects, subjects can include the elderly (e.g., >65 years old), children (e.g., <5 years old), hospitalized patients, healthcare workers, armed service and military personnel, food handlers, pregnant women, the chronically ill, and people traveling abroad. The compositions are generally suitable for these groups as well as the general population or as otherwise deemed necessary by a physician.

**KITS**

[0116] The application also provides, and the means of the invention can be suitable for being comprised in kits comprising one or more containers of compositions of the application or invention. Compositions can be in liquid form or can be lyophilized. Suitable containers for the compositions include, for example, bottles, vials, sy-
rings, and test tubes. Containers can be formed from a variety of materials, including glass or plastic. A container can have a sterile access port (for example, the container can be an intravenous solution bag or a vial having a stopper piercable by a hypodermic injection needle).

**[0117]** The kit can further comprise a second container comprising a pharmaceutically-acceptable buffer, such as phosphate-buffered saline, Ringer’s solution, or dextrose solution. It can also contain other materials useful to the end-user, including other pharmaceutically acceptable formulating solutions such as buffers, diluents, filters, needles, and syringes or other delivery device(s). The kit can further include a third component comprising an adjuvant.

**[0118]** The kit can also comprise a package insert containing written instructions for methods of inducing immunity, preventing infections, or for treating infections. The package insert can be an unapproved draft package insert or can be a package insert approved by the Food and Drug Administration (FDA) or other regulatory body.

**[0119]** The application also provides, and the means of the invention can be suitable for being comprised in a delivery device pre-filled with the compositions of the application or invention.

**[0120]** The pharmaceutical compositions are generally formulated as sterile, substantially isotonic and in full compliance with all Good Manufacturing Practice (GMP) regulations of the U.S. Food and Drug Administration.

**[0121]** From the foregoing description, various modifications and changes in the compositions and methods will occur to those skilled in the art. All such modifications coming within the scope of the appended claims are intended to be included therein. Each recited range includes all combinations and sub-combinations of ranges, as well as specific numerals contained therein.

**[0122]** Although the foregoing application or invention has been described in detail by way of example for purposes of clarity of understanding, i.e., by way of illustration not limitation, it will be apparent to the artisan that certain changes and modifications are comprehended by the disclosure and can be practiced without undue experimentation within the scope of the appended claims.

**EXEMPLARY ASPECTS**

**[0123]** Below are examples of specific aspects for carrying out the means of the application or invention. The examples are offered for illustrative purposes only, and are not intended to limit the scope of the application or invention in any way. Efforts have been made to ensure accuracy with respect to numbers used (e.g., amounts, temperatures, and the like), but some experimental error and deviation should, of course, be allowed for.

**MATERIALS AND METHODS**

**Bacterial Strains and Growth Conditions**

**[0125]** The bacterial strain used in this study is B. pertussis BPZE1, a streptomycin-resistant TohamaI derivative deleted for the dermonecrotic (DNT)-encoding gene, producing inactivated pertussis toxin (PT) and background levels of tracheal cytotoxin (TCT) (22). BPZE1 bacteria were grown at 37°C for 72 h on Bordet-Gengou (BG) agar (Difco, Detroit, Mich.) supplemented with 1% glycerol, 10% defibrinated sheep blood and 100 µg/ml streptomycin (Sigma Chemical Co., St Louis, Mo.). Liquid cultures were performed as described previously (Menozzi FD, et al., “Identification and purification of transferring- and lactoferrin-binding proteins of Bordetella pertussis and Bordetella bronchiseptica”, Infect. Immun 59: 3982-3988, 1991) in Stainer-Scholte (SS) medium containing 1 g/l heptakis(2,6-di-O-methyl) β-cyclodextrin (Sigma). Heat-inactivation was performed at 95°C for 1 hour.

**[0126]** Intranasal Infections. Six to eight week-old female Balb/c mice were kept under specific pathogen-free conditions in Individual Ventilated Cages, and all experiments were carried out under the guidelines of the National University of Singapore animal study board. For BPZE1 treatment, sedated mice were intranasally administered once, twice or three times (as indicated) with approximately 5 × 10^6 colony-forming units (cfu) of live or dead BPZE1 bacteria in 20 µl sterile PBS supplemented with 0.05% Tween80 (Sigma) (PBST) as previously described (Mielcarek N, et al., "Intranasal priming with recombinant Bordetella pertussis for the induction of a systemic immune response against a heterologous antigen", Infect immune 65: 544-550, 1997). For influenza infection, sedated mice were nasally administered with approximately 2 × 10^6 TCID₅₀ of mouse-adapted A/Inachi/2/68 (H3N2) virus passage 10 (Narasaraju T, et al., "Adaptation of human influenza H3N2 virus in a mouse pneumonitis model: insights into viral virulence, tissue tropism and host pathogenesis", Microbes Infect 11: 2-11, 2009) or 4 lethal dose (LD)₅₀ of H1N1 (A/PR/8/34) influenza virus (ATCC# VR-95) in 20 µl sterile PBS supplemented with penicillin and streptomycin. Ten mice per group were used to determine the survival rates based on body weight loss and the mice were euthanized when body weight loss exceeded 20% of the original body weight.

**Intranasal Infections.**
TCID50 was determined by a reduction in cytopathic effect (CPE) of 50%, and the log TCID50/lung was derived. Five mice per group per time point were individually assessed.

**Viral Titer Determination**

Mouse lungs were harvested and homogenized using mechanical disruption (Omniprobe homogenizer), and tested for the presence of viable virus by tissue culture infectious dose 50 (TCID50) assay using a modified method reported by the WHO (WHO, "WHO Manual on Animals Influenza Diagnosis and Surveillance" (World Health Organization, Geneva), 2002). Briefly, 90% confluent Madin-Darby Canine Kidney (MDCK) cells in 96-well plates were inoculated with 100 μl of 10-fold serially diluted lung homogenates. Plates were incubated at 35°C in a humidified incubator (5% CO2) for 3 days. TCID50 was determined by a reduction in cytopathic effect (CPE) of 50%, and the log TCID50/lung was derived. Five mice per group per time point were individually assessed.

**Histopathologic Examination**

Four mice per group were sacrificed and their lungs were harvested 3 days post-viral challenge. The lungs were removed and fixed in 10% formalin in PBS. After fixation, the lungs were embedded in paraffin, sectioned, and stained with H&E.

**Cellular Infiltrates in Bronchoalveolar Lavage Fluids (BALFs)**

Individual BALFs were recovered by injecting 1 ml of sterile PBS into the lungs of sacrificed animals and performing one lavage step ensuring that both lungs inflated during the process. BALFs were then centrifuged at 400g for 10 min, and the supernatant was removed and stored at -80°C for cytokine detection. Total BALF cell number was determined using a hemocytometer. The cells were spotted onto a glass slide using a Cytospin device (Thermo Shandon), and were stained with a modified Wright staining procedure (Kimman TG, et al., "Development and antigen specificity of the lymphoproliferation response of pigs to pseudorabies virus: dichotomy between secondary B- and T-cell responses", Immunology 86: 372-378, 1995). Identification of the different cell types was performed using standard morphological criteria. Results are expressed as the percentage of each cell type in the total cell population. A total of 500 cells were considered per slide. Four mice per group were individually assessed.

**FACS Analysis**

Mice were sacrificed, their lungs were harvested and single cell suspensions were prepared by digesting the lungs at 37°C for 15 min in 2 ml digestion buffer containing 0.5 mg/ml Liberase (Roche) in RPMI with 1% FCS and 2 U/ml DNasel (Qiagen), followed by centrifugation on Ficoll-PaqueTM PLUS (GE) for 20 min at 600g and room temperature. Cells were collected and washed twice with sterile FACS buffer (2% FCS, 5 mM EDTA in PBS). 10^6 cells were stained with FITC-labeled anti-mouse CD3 antibody (eBioscience) and analyzed on CyAnTM ADP cytometer (Dako). Five mice per group per time point were individually assessed.

**Cytokine and Chemokine Analysis**

A high titer anti-B. pertussis immune serum was generated in 10 adult Balb/c mice nasally infected twice at a 4-week interval with 5 x 10^8 cfu of live BPZE1 bacteria. Another group of 10 adult naive Balb/c mice were injected intraperitoneally (ip.) with 10^5.5 TCID50 of heat-inactivated human /Aichi/2/68 (H3N2) virus (HI-H3N2) in complete Freund’s adjuvant and boosted with the same amount of HI-H3N2 virus in incomplete Freund’s adjuvant 2 weeks later. The immune sera from each mouse group were collected 2 weeks after the boost, pooled, and the anti-pertussis and anti-influenza antibody titers were measured by ELISA. Moreover, HI-H3N2 serum was tested for the presence of neutralizing antibodies by neutralization assay. The immune sera were filter-sterilized, heat inactivated at 56°C for 30 min and stored at -80°C until further use. Sera from control naive mice were also collected as negative control.

**Passive Transfer Experiment**

Six to eight week-old recipient Balb/c mice were ip. injected with 200 μl of naive, anti-BPZE1 or anti-H3N2 immune serum 1 day prior viral challenge with mouse-adapted H3N2 virus. Body weight losses were monitored to determine the survival rates. Ten mice per group were assayed.

**T Cell Proliferation assay**

Lymphocyte proliferation was measured by incorporation of tritiated (3H) thymidine as described elsewhere (Bao Z, et al., "Glycogen synthase kinase-3beta inhibition attenuates asthma in mice", Am J Respir Crit Care Med 176: 431-438, 2007). Briefly, spleens from naive and BPZE1-treated mice (6 mice per group) were collected under aseptic condition and pooled. Single-cell
EXAMPLE 1: A SINGLE NASAL ADMINISTRATION OF LIVE ATTENUATED BORDETELLA PERTUSSIS PROTECTS AGAINST H3N2 INFLUENZA CHALLENGE.

EXAMPLE 2: LIVE BUT NOT DEAD BPZE1 BACTERIA PROTECT AGAINST LETHAL H3N2 CHALLENGE.

[0139] Adult Balb/c mice were nasally inoculated with live BPZE1 bacteria and subsequently challenged either 3 or 6 weeks later with a lethal dose of mouse-adapted H3N2 virus. Survival rate based on body weight changes indicated that the mice challenged 3 weeks after nasal BPZE1 treatment were not significantly protected whereas 60% protection was achieved when mice were challenged 6 weeks post-BPZE1 treatment (Fig. 1).

EXAMPLE 3: BOOST EFFECT.

[0140] Live BPZE1 bacteria were nasally administered to Balb/c mice twice at a 4-week interval prior lethal challenge with mouse-adapted H3N2 virus 6 weeks post-BPZE1 treatment. The results showed that dead bacteria did not provide any significant protection against H3N2 (Fig. 2), suggesting that bacterial colonization of the mouse lung is necessary to induce the protective mechanisms.

Statistical Analysis

[0136] Unless otherwise stated, bars represent means ± SD and averages were compared using a bidirectional unpaired Student’s t test with a 5% significance level with * p≤0.05, **p≤0.01 and ***p≤0.001.
EXAMPLE 4: BPZE1 BACTERIA PROVIDE PROTECTION AGAINST H1N1 VIRUS CHALLENGE

[0141] The protective potential of BPZE1 bacteria against influenza A viruses was further explored. Mice nasally treated once with live BPZE1 bacteria were not protected against a lethal challenge with human A/PR/8/34 (H1N1) influenza A virus performed 6 weeks later (data not shown). However, three consecutive administrations of live BPZE1 bacteria conferred 50% protection against H1N1 virus (Fig. 4). These observations indicated that BPZE1 bacteria can have the potential to protect against all influenza A viruses although with a variable efficacy.

EXAMPLE 5: THE VIRAL LOAD IS NOT REDUCED IN THE PROTECTED MICE.

[0142] To further characterize the cross-protection against influenza A viruses, the viral load was quantified in the lungs of mice treated twice with BPZE1 bacteria and in control mice. The virus load was checked 3 days post-infection which corresponds to the peak of virus titer in mice infected with mouse-adapted H3N2 virus (Narasaraju T, et al., "Adaptation of human influenza H3N2 virus in a mouse pneumonitis model: insights into viral virulence, tissue tropism and host pathogenesis", Microbes Infect 11: 2-11, 2009). No significant difference in the viral load was observed between the two animal groups (Fig. 5). This result suggested that the cross-protective mechanisms triggered in the BPZE1-treated animals do not directly target the virus particles and/or infected cells.

EXAMPLE 6: BPZE1 TREATMENT PROTECTS MICE FROM INFLUENZA-INDUCED IMMUNOPATHOLOGY AND LYMPHOCYTE DEPLETION.

[0143] Lung immunopathology was examined by histology of lung sections from infected BPZE1-treated animals and control mice. As expected and as described previously (Narasaraju T, et al., "Adaptation of human influenza H3N2 virus in a mouse pneumonitis model: insights into viral virulence, tissue tropism and host pathogenesis", Microbes Infect 11: 2-11, 2009), the infected control mice displayed severe inflammation with inflammatory cells, severe bronchopneumonia and interstitial pneumonitis with bronchioles and alveoli filled with necrotic debris as well as high pulmonary emphysema and moderate edema (Fig 7A). In contrast, only mild inflammation, minimal airway and alveolar damage, and mild perivascular/peribronchular damage associated with minimal edema were observed in the lungs of the protected BPZE1-treated mice.

[0144] The cell populations present in the broncho-alveolar lavage fluids (BALFs) recovered from protected and non-protected animals were also examined. Whereas the total number of cells present in the BALFs from both animal groups were comparable (11.8 x 10^5 versus 16.1 x 10^5), a significantly higher number of macrophages and lower number of neutrophils were found in the BPZE1-treated mice (Fig. 6B).

[0145] Furthermore, the lymphocyte population present in the lungs of protected and non-protected mice was analysed. Lymphocyte depletion has indeed been reported in mice infected with highly pathogenic H1N1 (1918) and H5N1 influenza viruses (Kash JC, et al., "Genomic analysis of increased host immune and cell death responses induced by 1918 influenza virus", Nature 443: 578-581, 2006; Uiprasertkul M, et al., "Apoptosis and Pathogenesis of Avian Influenza A (H5N1) Virus in Humans", Emerg Infect Dis 13: 708-712, 2007; Lu X, et al., "A mouse model for the evaluation of pathogenesis and immunity to influenza A (H5N1) viruses isolated from humans", J Virol 73: 5903-5911, 1999) as well as in mice infected with the mouse-adapted H3N2 virus strain used in this work (Narasaraju T, et al., "Adaptation of human influenza H3N2 virus in a mouse pneumonitis model: insights into viral virulence, tissue tropism and host pathogenesis", Microbes Infect 11: 2-11, 2009). Here, Balb/c mice were treated twice with BPZE1 bacteria and challenged with mouse-adapted H3N2 virus 4 weeks later. The mouse lungs were harvested 3 and 5 days post-influenza challenge for FACS analysis of the T cell population. Three days post-viral challenge, the percentage of CD3⁺ T lymphocytes in the infected control mice and BPZE1-treated mice was comparable to the percentage found in the animals before challenge (Fig. 6C). However, a significant CD3⁺ T cell depletion was observed in the infected control animals 5 days post-viral challenge (Fig 6C) as reported before (Narasaraju T, et al., "Adaptation of human influenza H3N2 virus in a mouse pneumonitis model: insights into viral virulence, tissue tropism and host pathogenesis", Microbes Infect 11: 2-11, 2009). In contrast, the T cell population remained constant before and after challenge in the protected BPZE1-immunized animals (Fig. 6C), suggesting that BPZE1-treatment prevented influenza-induced lymphocyte depletion.

EXAMPLE 7: THE PRODUCTION OF PRO-INFLAMMATORY CYTOKINES AND CHEMOKINES IS DAMPENED IN THE PROTECTED BPZE1-TREATED MICE.

[0146] Major pro-inflammatory cytokines and chemokines were measured in the BALFs recovered from protected BPZE1-treated mice and compared to non-protected mice, 1 and 3 days after lethal H3N2 virus challenge. All the pro-inflammatory cytokines and chemokines measured in the BALFs of the protected animal group were significantly lower than those measured in the non-protected mice (Fig. 7). The differences were observed at both day 1 and day 3 for IL-1β, IL-6, IFN-γ and TNF-α, which are the main pro-inflammatory cytokines contributing to influenza-induced immunopathology and correlating with disease severity (de Jong MD,
et al., "Fatal outcome of human influenza A (H5N1) is associated with high viral load and hypercytokinemia", Nat Med 12: 1203-1207, 2006; Beigel JH, et al., "Avian influenza A (H5N1) infection in humans", N Engl J Med 353: 1374-1385, 2005; Peiris JS, et al., "Re-emergence of fatal human influenza A subtype H5N1 disease", Lancet 363: 617-619, 2004; Schmitz N, et al., "Interleukin-1 is responsible for acute lung immunopathology but increases survival of respiratory influenza virus infection", J Virol 79: 6441-6448, 2005). The levels of IFN-α, MCP-1 and RANTES were found significantly reduced 1 day post-viral challenge whereas the production of IL-12(p70), GM-CSF and KC was lower at day 3 post-challenge. Strikingly, complete suppression of IL-12 production was found in the protected animal group, consistent with lower levels of IFN-γ.

**EXAMPLE 8: B. PERTUSSIS-SPECIFIC ADAPTIVE IMMUNITY IS NOT INVOLVED IN THE CROSS-PROTECTION.**

The presence of cross-reactive (and protective) antibodies and/or T cells in the BPZE1-treated animals was examined. Firstly, a BLAST search failed to identify any matching epitopes between B. pertussis and influenza A H3N2 and H1N1 viruses (data not shown). Secondly, the immune serum from BPZE1-treated mice did not react with whole H3N2 viral particles in an ELISA assay, neither did it neutralize the virus in an in vitro neutralization assay (data not shown). Thirdly, a high-titer anti-BPZE1 immune serum did not confer any protection against H3N2 lethal challenge in an in vivo passive transfer experiment whereas an immune serum raised against heat-inactivated H3N2 virus gave a 100% protection rate (Fig. 8A). Fourthly, proliferation and IFN-γ ELISPOT assays showed that splenocytes from BPZE1-treated mice did not proliferate and did not produce IFN-γ respectively upon stimulation with H3N2 viral particles (Fig. 8B & C). Altogether, these data strongly support that *B. pertussis*-specific immunity does not play any role in the cross-protection against influenza A viruses.

**DISCUSSION**

Severe respiratory disease and immunopathology together with a high case-fatality rate have become a hallmark of highly pathogenic avian influenza virus infection in humans as well as in other mammalian species. However, the underlying mechanisms accounting for the severe immunopathological effects have yet to be fully elucidated. In particular, relationship between viral load, immunopathology and disease outcome remains elusive. Several previous studies have reported a reduced mortality rate and immunopathology without significant reduction of the viral burden in animal models of influenza infection; For example, reduced inflammatory cell infiltration and pulmonary damage but with delayed viral clearance was observed in mice with disrupted MIP-1α gene (Cook DN, et al., "Requirement of MIP-1 alpha for an inflammatory response to viral infection". Science 269: 1583-1585, 1995). Likewise, CCR2 (primary receptor for MCP-1)-deficient mice displayed reduced mortality but a significantly elevated viral burden associated with decreased pulmonary cell infiltration and tissue damage (Dawson TC, et al., "Contrasting effects of CCR5 and CCR2 deficiency in the pulmonary inflammatory response to influenza A virus", Am J Pathol 156: 1951-1959, 2000). In contrast, IL-1R knock-out mice showed increased mortality associated with delayed viral clearance but less severe pathology (Schmitz N, et al., "Interleukin-1 is responsible for acute lung immunopathology but increases survival of respiratory influenza virus infection", J Virol 79: 6441-6448, 2005).

suggest a key role for an excessive host response in mediating at least some of the extreme pathology associated with highly pathogenic influenza viruses. However, the role of each individual cytokine during influenza infection has remained unclear with often both positive and negative effects; Although their production can be important for viral clearance through the recruitment and/or activation of immune effector cells on the site of infection, their inflammatory properties can also lead to tissue damage (La Gruta NL, et al., "A question of self-preservation: immunopathology in influenza virus infection", Immunol Cell Biol 85: 85-92 2007).

[0151] The reduced production of pro-inflammatory cytokines and chemokines in the respiratory tract of the protected BPZE1-treated animals likely impacted on cellular infiltration and immune cell activation; A significantly lower neutrophil counts was indeed observed in the BALFs of the protected animals consistent with lower levels of KC and TNF-α, both cytokines being involved in the recruitment and activation of neutrophils in the infected tissues (La Gruta NL, et al., "A question of self-preservation: immunopathology in influenza virus infection", Immunol Cell Biol 85: 85-92 2007; Kips JC, et al., "Tumor necrosis factor causes bronchial hyperresponsiveness in rats", Am Rev Respir Dis 145: 332-336, 1992; Headley AS, et al., "Infections and the inflammatory response in acute respiratory distress syndrome", Chest 111: 1306-1321, 1997). Furthermore, the suppressed production of IL-12 measured in the protected animals likely impacted on cellular infiltration and immune cell activation; A significantly lower neutrophil counts was indeed observed in the BALFs of the protected animals consistent with lower levels of KC and TNF-α, both cytokines being involved in the recruitment and activation of neutrophils in the infected tissues (La Gruta NL, et al., "A question of self-preservation: immunopathology in influenza virus infection", Immunol Cell Biol 85: 85-92 2007; Kips JC, et al., "Tumor necrosis factor causes bronchial hyperresponsiveness in rats", Am Rev Respir Dis 145: 332-336, 1992; Headley AS, et al., "Infections and the inflammatory response in acute respiratory distress syndrome", Chest 111: 1306-1321, 1997). Furthermore, the suppressed production of IL-12 measured in the protected animals likely impaired the activation of some immune cells such as natural killer (NK) cells and cytotoxic CD8+ T cells. Both cell types have been described potentially harmful and involved in immunopathology upon release of inflammatory mediators (La Gruta NL, et al., "A question of self-preservation: immunopathology in influenza virus infection", Immunol Cell Biol 85: 85-92 2007). Consistently, IFN-γ production, a hallmark for NK and CD8+ T cell activation, was found significantly lower in the BALFs recovered from the protected animals. In addition, the lower IFN-γ production can affect the neutrophil responses to the virus, including oxidative burst, induction of antigen presentation and chemokine production (Ellis TN and Beaman BL, "Interferon-gamma activation of polymorphonuclear neutrophil function", Immunology 112: 2-11, 2004; Farrar MA and Schreiber RD, "The molecular cell biology of interferon-gamma and its receptor", Annu Rev Immunol 11: 571, 1993).

[0152] Interestingly, a significantly higher number of macrophages were observed in the BALFs of protected BPZE1-treated mice despite lower levels of MCP-1 and GM-CSF, involved in monocytes recruitment and differentiation into macrophages, respectively. However, note should be taken that alveolar macrophages (AM) and not tissue resident macrophages constitute the main macrophage population recovered in the BALFs (Jakubzick C, et al., "Modulation of dendritic cells trafficking to and from the airways", J Immunol 176: 3578-3584, 2006). It is thus conceivable that the protected mice can display a reduced macrophage population in their lung tissues compared to infected control mice.

[0153] AM have been shown to display suppressive effects on the inflammation reaction by regulating T-cell function (Strickland DH, et al., "Regulation of T-cell function in lung tissue by pulmonary alveolar macrophages", Immunology 80: 266-272, 1993), and by suppressing dendritic cells maturation (Holt PG, et al., "Down-regulation of the antigen presenting function(s) of pulmonary dendritic cells in vivo by resident alveolar macrophages", J Exp Med 177: 397-407, 1993; Bilyk N and Holt PG, "Inhibition of the immunosuppressive activity of resident pulmonary alveolar macrophages by granulocyte/macrophage colony stimulating factor", J Exp Med 177: 1773-1777, 1993; Stumbles PA, et al., "Airway dendritic cells: co-ordinators of immunological homeostasis and immunity in the respiratory tract", APMIS 111: 741-755, 2003) and migration to the mesenteric lymph nodes (Jakubzick C, et al., "Modulation of dendritic cells trafficking to and from the airways", J Immunol 176: 3578-3584, 2006). One can thus hypothesize that the higher number of alveolar macrophages induced upon influenza challenge contributed to the suppression/control of the inflammation in the protected BPZE1-treated animals.

[0154] Furthermore, we found that the CD3+ T cell population remained unchanged in the protected BPZE1-treated animals upon viral challenge whereas a significant reduction in the proportion of CD3+ T cells was found in the infected control mice. Lymphocyte depletion during highly pathogenic influenza infection has been previously reported (Kash JC, et al., "Genomic analysis of increased host immune and cell death responses induced by 1918 influenza virus", Nature 443: 578-581, 2006; Uiprasertkul M, et al., "Apoptosis and Pathogenesis of Avian Influenza A (H5N1) Virus in Humans", Emerg Infect Dis 13: 708-712, 2007; Narasaraju T, et al., "Adaptation of human influenza H3N2 virus in a mouse pneumonitis model: insights into viral virulence, tissue tropism and host pathogenesis", Microbes Infect 11: 2-11, 2009; Lu X, et al., "A mouse model for the evaluation of pathogenesis and immunity to influenza A (H5N1) viruses isolated from humans", J Virol 75: 5903-5911, 1999) and experimental evidences have suggested apoptosis as a potential mechanism (Uiprasertkul M, et al., "Apoptosis and Pathogenesis of Avian Influenza A (H5N1) Virus in Humans", Emerg Infect Dis 13: 708-712, 2007; Lu X, et al., "A mouse model for the evaluation of pathogenesis and immunity to influenza A (H5N1) viruses isolated from humans", J Virol 75: 5903-5911, 1999). Since no difference in the viral load was observed between protected and non-protected animals, lymphocyte apoptosis can thus not be a direct cytolitic effect of the virus itself. Instead, our data are consistent with previous studies which suggested that in H5N1-infected humans and mice, lymphocyte apoptosis was likely caused by cytokine dysregulation and overactivation of the host immune response (Uiprasertkul M, et al., "Apoptosis and Pathogenesis of Avian Influenza A (H5N1) Virus in Humans", Emerg Infect
Much of the activity of B. pertussis virulence factors is dedicated to immunomodulation so as to suppress, subvert and evade the host defense system (Carbonetti NH, "Immunomodulation in the pathogenesis of Bordetella pertussis infection and disease", Curr Opin Pharmacol 7: 1-7, 2007). The immune response to B. pertussis is initiated and controlled through toll-like receptor (TLR)-4 signaling, inducing the anti-inflammatory cytokine IL-10 production by dendritic cells (DCs) which could inhibit inflammatory responses and limit pathology in the airways (Higgins SC, et al., "Toll-like receptor 4-mediated innate IL-10 activates antigen-specific regulatory T cells and confers resistance to Bordetella pertussis by inhibiting inflammatory pathology", J Immunol 171: 3119-3127, 2003). Filamentous hemagglutinin (FHA), the major adhesin produced in B. pertussis, was shown to stimulate IL-10 production and inhibit TLR-induced IL-12 production by macrophages and DCs, resulting in the development of IL-10 secreting type 1 T-regulatory (Tr1) cells (McGuirk P, et al., "Pathogen-specific T regulatory 1 cells induced in the respiratory tract by a bacterial molecule that stimulates interleukin 10 production by dendritic cells: a novel strategy for evasion of protective T helper type 1 responses by Bordetella pertussis", J Exp Med 195: 221-231, 2002). Interestingly, the systemic administration of FHA was recently found to reduce intestinal inflammation in a T-cell mediated model of colitis, supporting the anti-inflammatory role of FHA (Braat H, et al., "Prevention of experimental colitis by parenteral administration of a pathogen-derived immunomodulatory molecule", Gut 56: 351-357, 2007). However, here no difference in the production of IL-10 and TGF-β was found between protected and non-protected mice, ruling out a potential involvement of FHA-mediated induction of Tr1 in the cross-protection against influenza A viruses conferred by B. pertussis.

We report here that in a Balb/c mouse model of severe pneumonitis, prior nasal administration of an attenuated strain of Bordetella pertussis (BPZE1), the etiologic agent of whooping cough, provided effective and sustained protection against lethal challenge with a mouse-adapted H3N2 influenza A virus and to a lesser extent against human H1N1 (A/PR/8/34) influenza A virus. Although the cellular and molecular players involved in this cross-protection have yet to be identified, our data indicate that B. pertussis-specific adaptive immunity and Tr1-mediated down-regulation are likely not involved. Importantly, we found that the cross-protection does not result in viral load reduction. Instead, protected BPZE1-treated mice displayed minimal lung immunopathology, consistent with reduced neutrophil infiltration and lower production of a variety of major pro-inflammatory cytokines and chemokines in their BALFs. Our findings thus strongly suggest that protection against influenza A viruses induced-lethal pneumonitis can be achieved through attenuation of inflammation and dampening of the cytokine storm, and demonstrate the potential use of BPZE1 bacteria as an effective prophylactic means of protecting against virulent influenza A virus infections.

Claims

1. A composition for use in the treatment or prevention of an Influenza infection in a mammal, wherein said composition comprises an attenuated Bordetella strain, wherein said attenuated Bordetella strain is a mutated Bordetella strain comprising:

   a mutated pertussis toxin (ptx) gene, a deleted or mutated dermonecrotic (dnt) gene, and a heterologous ampG gene, and wherein said mutated Bordetella strain does not comprise a heterologous expression platform carrying heterologous antigens, said heterologous expression platform being used to deliver the heterologous antigens to the respiratory mucosa of a mammal.

2. The composition for use in the treatment or prevention of an Influenza infection in a mammal according to claim 1, wherein the Bordetella strain comprises a Bordetella pertussis strain.

3. The composition for use in the treatment or prevention of an Influenza infection in a mammal according to claim 1 or 2, wherein said mutated ptx gene results in the substitution of an amino acid involved in substrate binding.

4. The composition for use in the treatment or prevention of an Influenza infection in a mammal according to claim 3, wherein the mutation of the ptx gene results in the substitution of an amino acid involved in catalysis.

5. The composition for use in the treatment or prevention of an Influenza infection in a mammal according to claim 4, wherein the substitution of the amino acid involved in substrate binding comprises K9R.

6. The composition for use in the treatment or prevention of an Influenza infection in a mammal according to any one of claims 3-5, wherein the mutation of the ptx gene results in the substitution of an amino acid involved in catalysis.

7. The composition for use in the treatment or prevention of an Influenza infection in a mammal according to claim 6, wherein the substitution of the amino acid involved in catalysis comprises E129G.

8. The composition for use in the treatment or prevention of an Influenza infection in a mammal according to any one of claims 1-7, wherein said dnt gene is deleted.

9. The composition for use in the treatment or prevention of an Influenza infection in a mammal according to any one of claims 1-7, wherein said dnt gene is mutated.

10. The composition for use in the treatment or prevention of an Influenza infection in a mammal according to claim 9, wherein said mutated dnt gene codes for a protein having a deficient DNT enzymatic activity, wherein said mutated dnt gene is mutated by point mutation, and wherein said mutated dnt gene is mutated to encode Ala-1305 instead of Cys-1305.

11. The composition for use in the treatment or prevention of an Influenza infection in a mammal according to any one of claims 1-10, wherein said heterologous
ampG gene replaces the endogenous Bordetella ampG gene.

12. The composition for use in the treatment or prevention of an Influenza infection in a mammal according to claim 11, wherein said heterologous ampG gene is the ampG gene of an E. coli strain.

13. The composition for use in the treatment or prevention of an Influenza infection in a mammal according to claim 11 or 12, wherein said mutated Bordetella strain expresses less than 1% residual Tracheal CytoToxin (TCT) activity.

14. The composition for use in the treatment or prevention of an Influenza infection in a mammal according to any one of claims 1-13, wherein attenuated Bordetella strain is the strain identified by accession number CNCM I-3585 deposited with the Collection Nationale de Cultures de Microorganismes (CNCM) in Paris, France under the Budapest Treaty on March 9, 2006.

15. The composition for use in the treatment or prevention of an Influenza infection in a mammal according to any one of claims 1-14, wherein said mutated Bordetella strain further comprises a mutated Bvg-regulated gene selected from a deficient adenylate cyclase (AC) gene, a deficient lipopolysaccharide (LPS) gene and a deficient filamentous hemagglutinin (FHA) gene.

Patentansprüche

1. Zusammensetzung zur Verwendung bei der Behandlung oder Vorbeugung einer Influenza-Infektion bei einem Säuger, worin die Zusammensetzung einen abgeschwächten Bordetella-Stamm umfasst, worin der abgeschwächte Bordetella-Stamm ein mutierter Bordetella-Stamm ist, umfassend:
ein mutiertes Pertussistoxin(ptx)-Gen,
ein deletiertes oder mutiertes Dermonekrose (dnt)-Gen und
ein heterologes ampG-Gen, und worin der mutierte Bordetella-Stamm keine heterologe Antigene tragende heterologe Expressionsplattform umfasst, wobei die heterologe Expressionsplattform verwendet wird, um die heterologen Antigene der Schleimhaut der Atemwege eines Säugers zur Verfügung zu stellen.

2. Zusammensetzung zur Verwendung bei der Behandlung oder Vorbeugung einer Influenza-Infektion bei einem Säuger gemäß Anspruch 1, worin der Bordetella-Stamm einen Bordetella-Pertussis-Stamm umfasst.

3. Zusammensetzung zur Verwendung bei der Behandlung oder Verfolgung einer Influenza-Infektion bei einem Säuger gemäß Anspruch 1 oder 2, worin das mutierte ptx-Gen für ein PTX-Protein kodiert, dessen S1-Rest enzymatisch inaktiv, aber noch immunologisch aktiv ist.

5. Zusammensetzung zur Verwendung bei der Behandlung oder Vorbeugung einer Influenza-Infektion bei einem Säuger gemäß Anspruch 4, worin die Substitution der bei der Substratbindung involvierten Aminosäure K9R umfasst.

10. Zusammensetzung zur Verwendung bei der Behandlung oder Vorbeugung einer Influenza-Infektion bei einem Säuger gemäß Anspruch 9, worin das mutierte dnt-Gen für ein Protein kodiert, das eine definierte DNT-Enzymaktivität aufweist, worin das mutierte dnt-Gen durch eine Punktmutation mutiert ist und worin das mutierte dnt-Gen mutiert ist, um Ala-1305 anstelle von Cys-1305 zu kodieren.

13. Zusammensetzung zur Verwendung bei der Behandlung oder Vorbeugung einer Influenza-Infektion bei einem Säuger gemäß Anspruch 11 oder 12, worin der mutierte Bordetella-Stamm weniger als 1% Residualtracheal-CytoToxin (TCT)-Aktivität exprimiert.

Revendications

1. Composition destinée à une utilisation dans le traitement ou la prévention d’une infection par Influenza chez un mammifère, dans laquelle ladite composition comprend une souche atténuée de Bordetella, dans laquelle ladite souche atténuée de Bordetella est une souche mutée de Bordetella comprenant :

   un gène muté de toxine de la coqueluche (ptx),
   un gène déleté ou muté dermonécrotique (dnt), et
   un gène ampG hétérologue, et dans laquelle ladite souche mutée de Bordetella ne comporte pas de plate-forme d’expression hétérologue portant des antigènes hétérologues, ladite plate-forme d’expression hétérologue étant utilisée pour administrer les antigènes hétérologues à la muqueuse respiratoire d’un mammifère.

2. Composition destinée à une utilisation dans le traitement ou la prévention d’une infection par Influenza chez un mammifère selon la revendication 1, dans laquelle la souche de Bordetella comprend une souche de Bordetella pertussis.

3. Composition destinée à une utilisation dans le traitement ou la prévention d’une infection par Influenza chez un mammifère selon la revendication 1 ou 2, dans laquelle ledit gène ptx muté code pour une protéine PTX, dont la partie SI est enzymatiquement inactive, mais qui est encore immunologiquement active.

4. Composition destinée à une utilisation dans le traitement ou la prévention d’une infection par Influenza chez un mammifère selon la revendication 3, dans laquelle la mutation du gène ptx aboutit à une substitution d’un acide aminé impliqué dans la liaison au substrat.

5. Composition destinée à une utilisation dans le traitement ou la prévention d’une infection par Influenza chez un mammifère selon la revendication 4, dans laquelle la substitution de l’acide aminé impliqué dans la catalyse comprend K9R.

6. Composition destinée à une utilisation dans le traitement ou la prévention d’une infection par Influenza chez un mammifère selon la revendication 5, dans laquelle la substitution de l’acide aminé impliqué dans la catalyse comprend E129G.

7. Composition destinée à une utilisation dans le traitement ou la prévention d’une infection par Influenza chez un mammifère selon la revendication 6, dans laquelle la substitution de l’acide aminé impliqué dans la catalyse comprend K9R.

8. Composition destinée à une utilisation dans le traitement ou la prévention d’une infection par Influenza chez un mammifère selon la revendication 7, dans laquelle ledit gène dnt est délété.

9. Composition destinée à une utilisation dans le traitement ou la prévention d’une infection par Influenza chez un mammifère selon la revendication 9, dans laquelle ledit gène dnt est muté.

10. Composition destinée à une utilisation dans le traitement ou la prévention d’une infection par Influenza chez un mammifère selon la revendication 9, dans laquelle ledit gène dnt muté code pour une protéine ayant une activité enzymatique DNT déficiente, dans laquelle ledit gène dnt est muté par mutation ponctuelle, et dans laquelle ledit gène dnt muté est muté pour coder Ala-1305 au lieu de Cys-1305.
11. Composition destinée à une utilisation dans le traitement ou la prévention d’une infection par Influenza chez un mammifère selon l’une quelconque des revendications 1 à 10, dans laquelle ledit gène ampG hétérologue remplace le gène ampG endogène de Bordetella.

12. Composition destinée à une utilisation dans le traitement ou la prévention d’une infection par Influenza chez un mammifère selon la revendication 11, dans laquelle ledit gène ampG hétérologue est le gène ampG d’une souche d’E. coli.

13. Composition destinée à une utilisation dans le traitement ou la prévention d’une infection par Influenza chez un mammifère selon la revendication 11 ou 12, dans laquelle ladite souche mutée de Bordetella exprime moins de 1 % d’activité cytotoxine trachéale (TCT) résiduelle.

14. Composition destinée à une utilisation dans le traitement ou la prévention d’une infection par Influenza chez un mammifère selon l’une quelconque des revendications 1 à 13, dans laquelle ladite souche atténuée de Bordetella est la souche identifiée par le numéro d’ordre CNCM 1-3585 déposée auprès de la Collection Nationale de Cultures de Microorganismes (CNCM) à Paris, France, selon les termes du Traité de Budapest, le 9 mars 2006.

15. Composition destinée à une utilisation dans le traitement ou la prévention d’une infection par Influenza chez un mammifère selon l’une quelconque des revendications 1 à 14, dans laquelle ladite souche mutée de Bordetella comprend en outre un gène régulé par Bvg muté choisi parmi un gène d’adénylate cyclase (AC) déficient, un gène de lipopolysaccharide (LPS) déficient et un gène d’hémagglutinine filamentuse (FHA) déficient.
